C.2.        Saccharification Data	10
C.3.        Coproduct Composition	21
C.4.        Flour Data: Particle Size	23

## **Appendix A: Description of Analytical Methods**

The feedstock and solid coproducts were analyzed using NCERC standard operating procedures (SOP). This appendix provides simple descriptions of the methods that were used for each of these procedures.

### *A.1. Moisture (LMET 20.4)*

Moisture in corn flour and DDG/DDGS is determined by a loss-in-mass method that involves drying at 105 °C for 3 hours in a forced-air oven. This method is based on National Forage Testing Association (NFTA) method 2.2.2.5, which was recently recommended by a study funded by the American Feed Industry Association (AFIA), the Renewable Fuels Association (RFA), and the National Corn Growers Association (NCGA).

### *A.2. Particle-Size Distribution (LMET 18.1)*

The size-distribution of particles in DDG/DDGS and corn flour was determined by sieve analysis. This method involves adding 100 grams of the dry material to the top sieve in a stack of five sieves (No. 16, No. 20, No. 30, No. 40, No. 60; where larger number represents finer mesh size). The sieves are arranged such that the finest mesh screen (No. 60) is at the bottom and the coarsest mesh (No. 16) is at the top. A pan collects all material that passes through the finest screen. The sieves are shaken for 10 minutes in a mechanical sieve shaker. Then, the sieves are separated, and the mass of material remaining on each is measured. The size distribution is reported as the mass fraction of material collected on each sieve.

### *A.3. Starch/Total Fermentable Sugars (LMET 30.1 and 30.2)*

The concentration of total fermentable sugars (referred to as “starch” for simplicity) in corn flour and DDG/DDGS was measured using a procedure that is based on AOAC method 996.11. This method involves a combination of acid and enzymatic hydrolysis of starch and to glucose followed by quantitative analysis of the glucose concentration by high-performance liquid chromatography (HPLC). The distinction between this method and a true “starch” method is that a true starch method would include a washing step designed to remove soluble sugars before the acid digestion step.

Sample analysis involves incubation with 1-N hydrochloric acid at 60 °C, followed by neutralization and digestion with an alpha-amylase enzyme at its optimal temperature (usually 80 to 90 °C) for 90 minutes to extract and convert starch molecules to soluble oligosaccharides. Next, the pH of the slurry is adjusted to about 4.5 and the oligosaccharides are converted to glucose by incubation with a gluco-amylase enzyme at 50 °C for 24 hours. The concentration of glucose is then measured by HPLC.

### *A.4. Crude Protein (LMET 22.2)*

The concentration of crude protein was measured using a combustion procedure based on AOAC method 990.03. This instrumental method was recently recommended by a study funded by the American Feed Industry Association (AFIA), the Renewable Fuels Association (RFA), and the National Corn Growers Association (NCGA). At the NCERC, crude protein is measured by complete combustion of a sample to inorganic products (*e.g.*, NO<sub>x</sub>, SO<sub>x</sub>, CO, CO<sub>2</sub>, and ash) in an atmosphere of oxygen and carbon dioxide using an Elementar Rapid N III. The NO<sub>x</sub> is reduced to N<sub>2</sub>, CO is oxidized to CO<sub>2</sub>, and all other gaseous reactants and products are removed such that the concentration of N<sub>2</sub> in the gas stream can be measured by a thermal-conductivity

detector (TCD). Thus, the concentration of nitrogen in the sample is measured and the concentration of protein is estimated by applying a conversion factor of 6.25 g protein/g N.

#### *A.5. Crude Fat (LMET 19.2)*

Crude fat was measured using a modification of AOAC method 945.16. This method was recently recommended by a study funded by the American Feed Industry Association (AFIA), the Renewable Fuels Association (RFA), and the National Corn Growers Association (NCGA). Crude fat is measured by extraction of the sample with petroleum ether using an automated extraction system (Soxtec Avanti 2050). Samples to be analyzed are weighed into thimbles and inserted into the extraction unit and refluxed with petroleum ether for 6 hours. The solvent is recovered in a tared extraction cup, the solvent is evaporated, and the mass of the residue is measured to determine the concentration of petroleum-ether-extractable material (“crude fat”) in the sample.

#### *A.6. Crude Fiber (QC 3.5.1)*

Crude fiber was measured by a modification of AOAC method 978.10, which was recently recommended by a study funded by the American Feed Industry Association (AFIA), the Renewable Fuels Association (RFA), and the National Corn Growers Association (NCGA). Crude fiber analysis involves extraction of the sample with acetone, hot sulfuric acid, and hot sodium hydroxide in a FOSS Fibertec 2010 semi-automated extraction system. The mass of the residue remaining after extraction is dried, weighed, then completely combusted to ash in a muffle furnace at 550 °C. The mass of the residual ash is determined, and the concentration of the fiber is given by the ratio of the mass of volatile (at 550 °C) nonextractable material to the initial sample mass.

Crude fiber was originally intended to provide a measure of the concentrations of lignin plus cellulose, but the ADF method described below (section A.7) is more accurate.

#### *A.7. Acid-Detergent Fiber (ADF; QC 3.1.1)*

Acid-detergent fiber (ADF) was measured using a modification of AOAC method 973.18. This method involves extraction of the sample in an acid-detergent solution for two hours using a FOSS Fibertec 2010 semi-automated extraction system. The nonextractable residue is washed, dried, weighed, combusted to ash at 550 °C, and weighed again. The acid-detergent fiber is given by the ratio of the mass of the nonextractable, volatile (at 550 °C) material to the initial sample mass.

ADF is a measure of the sum of the concentrations of cellulose and lignin.

#### *A.8. Neutral-Detergent Fiber (NDF; QC 3.3.1)*

Neutral-detergent fiber was measured using AOAC method 2002:4. This method involves extraction of the sample with acetone to remove fat, followed by boiling in a neutral-detergent solution for one hour in the presence of a thermostable alpha-amylase enzyme using a FOSS Fibertec 2010 semi-automated extraction system. The nonextractable residue is washed with hot water, dried, weighed, and combusted to ash at 550 °C, and weighed again. The neutral-detergent fiber is given by the ratio of the mass of the nonextractable, volatile (at 550 °C) material to the initial sample mass.

NDF is a measure of the sum of the concentrations of lignin, cellulose, and hemicellulose.

## Appendix B: Derivation of Equation for Final Beer Volume

The volume of the beer ( $V_{\text{beer}}$ ; liters) at the end of fermentation is given by:

$$V_{\text{beer}} = \frac{M_{\text{water}} + C_{\text{EtOH}} V_{\text{beer}}}{\rho_{\text{mix}}} + \frac{C_{\text{ds}} V_{\text{beer}}}{\rho_{\text{ds}}} \quad (\text{B-1})$$

where  $M_{\text{water}}$  (kg) is the final mass of water after correcting for water lost due to starch hydrolysis,  $C_{\text{EtOH}}$  (kg/l) is the final concentration of ethanol,  $C_{\text{ds}}$  (kg/l) is the concentration of nonvolatile dissolved solids in the beer,  $\rho_{\text{mix}}$  is the density of the mixture, and  $\rho_{\text{ds}}$  is the density of the nonvolatile dissolved solids. The mass of water remaining at the end of fermentation is:

$$M_{\text{water}} = M_{\text{water,process}} + M_{\text{water,corn}} - M_{\text{water,hydrolysis}} \quad (\text{B-2})$$

where  $M_{\text{water,process}}$  (kg) is the mass of process water added to the fermentor,  $M_{\text{water,corn}}$  (kg) is the water that entered the fermentor as corn, and  $M_{\text{water,hydrolysis}}$  (kg) is the water consumed during hydrolysis. In this study, the sum of the mass of process water and the mass of water added with the corn were estimated experimentally from the fermentor fill mass,  $M_{\text{fermentor}}$  (kg) and the dry solids concentration of the mash ( $X_{\text{s,mash}}$ ; kg dry solids/kg mash):

$$M_{\text{water,process}} + M_{\text{water,corn}} = M_{\text{fermentor}} (1 - X_{\text{s,mash}}) \quad (\text{B-3})$$

The mass of water consumed during hydrolysis is given by:

$$M_{\text{water,hydrolysis}} = M_{\text{glucose}} - M_{\text{starch}} \quad (\text{B-4})$$

$M_{\text{glucose}}$  (kg) is the mass of glucose produced by hydrolysis of  $M_{\text{starch}}$  (kg) of starch. From the stoichiometry of starch hydrolysis, we know that 1.111 g glucose will be produced per gram of starch that is hydrolyzed. Therefore, the mass of water that is consumed during starch hydrolysis is proportional to the mass of glucose that is produced:

$$M_{\text{water,hydrolysis}} = M_{\text{glucose}} \left( \frac{0.111 \text{ g water/g starch}}{1.111 \text{ g glucose/g starch}} \right) \quad (\text{B-5})$$

Since there is also a stoichiometric relationship between glucose and ethanol, we know that 0.511 g ethanol are produced per gram of glucose, and the mass of water consumed in hydrolysis can be related to the amount of ethanol that is produced:

$$M_{\text{water,hydrolysis}} = M_{\text{EtOH}} \left( \frac{0.111 \text{ g water/g starch}}{(0.511 \text{ g ethanol/g glucose})(1.111 \text{ g glucose/g starch})} \right) \quad (\text{B-6})$$

or:

$$M_{\text{water,hydrolysis}} = C_{\text{EtOH}} V_{\text{beer}} \left( \frac{0.111 \text{ g water/g starch}}{(0.511 \text{ g ethanol/g glucose})(1.111 \text{ g glucose/g starch})} \right) \quad (\text{B-7})$$

Substituting Eqs. (B-2), (B-3), and (B-7) into Eq. (B-1) then simplifying gives:

$$V_{\text{beer}} = \frac{M_{\text{fermentor}} (1 - X_{s,\text{mash}})}{\rho_{\text{mix}} - C_{\text{EtOH}} \left\{ 1 - \left( \frac{0.111}{0.511 * 1.111} \right) \right\} - C_{ds} \left( \frac{\rho_{\text{mix}}}{\rho_{ds}} \right)} \quad (\text{B-8})$$

For the purpose of this analysis,  $C_{ds}$  was assumed to be 0.3 kg/l, which is equal to the value that was observed in a previous pilot-plant trial conducted at the NCERC, and  $\rho_{ds}$  was assumed to be 1.2 kg/l, which is approximately the density of protein. The density of the ethanol-water mixture ( $\rho_{\text{mix}}$ ) is given by:

$$\rho_{\text{mix}} = 0.1272 * C_{\text{EtOH}}^2 - 0.1848 * C_{\text{EtOH}} + 0.9956 \quad (\text{B-9})$$

which is based on data published in the *Perry's Chemical Engineers' Handbook* for the density of ethanol-water mixtures at 30 °C.
